# Outline

- Motivation
  - US Census of Agriculture
  - Potential uses of administrative data
- Methods
  - Triple-System Estimation
  - AI extension that uses neural networks
- Case Study and Simulation Results
- Conclusions

# Motivation – Census of Agriculture

- The Census of Agriculture is a complete count of U.S. farms, ranches, and producers
  - Conducted every 5 years; 2022 Census data recently published
- Based on Census Mailing List (CML)
  - Some undercoverage, mainly for smaller and newer farms
  - USDA definition of a farm is \$1,000 in sales or potential sales of agricultural products – can be very small farms

# Motivation – Census of Agriculture

- NASS uses the June Area Survey (JAS), an area frame survey, to adjust CML responses for:
  - Undercoverage
  - Nonresponse
  - Misclassification of farms as non-farms, and vice versa
- NASS uses a dual-system estimator based on CML and JAS as two independent lists

# Motivation – Farm Service Agency (FSA) Data as a Third List

- NASS uses FSA administrative data for a variety of purposes
  - Including list-building for the CML
- Using FSA as a third list may reduce variance, but
  - Most FSA records are referred onto the CML
  - Dependence between FSA list and NASS' pre-existing list frame
- A Triple-System Estimator (TSE) can account for list dependence, undercoverage, and nonresponse, using FSA records on the CML as a third list
- **We propose an Artificial-Intelligence TSE (AITSE) to better model nonlinear effects in the data**

# Methods – Splitting the CML to Bypass FSA Referral Problem

# Methods – Splitting the CML to Bypass FSA Referral Problem

# Methods – Triple-System Estimator

- The model uses a multivariate Bernoulli distribution
  - Different link functions to model different conditional list coverage probabilities
  - Allows calculation of conditional and marginal coverage
- Joint coverage and response probabilities are summed for CML respondents to estimate total number of farms

$$\hat{N}^* = \sum_{i \in C \cap R} \frac{1}{\hat{\pi}_{i,1111}^* + \hat{\pi}_{i,1101}^* + \hat{\pi}_{i,1011}^* + \hat{\pi}_{i,1001}^* + \hat{\pi}_{i,0111}^* + \hat{\pi}_{i,0011}^*}$$

Not on historical,  
on JAS, on FSA,  
responded

# Methods – Traditional Probability Models

- For given predictors  $X_1, X_2, \dots, X_p$ , the model is specified for a generic probability

$$\pi_{i,y_1y_2y_3y_4}^* = \Pr(Y_1 = y_1, Y_2 = y_2, Y_3 = y_3, Y_4 = y_4 | X_1, X_2, \dots, X_p),$$

where  $y_1, y_2, y_3, y_4 \in \{0, 1\}$  are binary observed responses

- Generalized linear model relates the mean of binary responses to the predictors via a link function  $h(\cdot)$  to perform regression as

$$h(\pi_{i,y_1y_2y_3y_4}^*) = \beta_0 + \beta_1 X_1 + \dots + \beta_p X_p$$

# Methods – AI Probability Models

- Based on the theory of additive logistic regression
- AI model relates the mean of binary responses to the predictors via logistic regression as

$$h(\pi_{i,y_1y_2y_3y_4}^*) = \beta_0 + \beta_1X_1 + \dots + \beta_pX_p + f_1(X_1, \dots, X_p) + \dots + f_m(X_1, \dots, X_p)$$

where the function

$$f_j(X_1, \dots, X_p) = g(\gamma_{j0} + \gamma_{j1}X_1 + \dots + \gamma_{jp}X_p)$$

for all  $j = 1, \dots, m$ , and a nonlinear activation function  $g(\cdot)$

- The model uses TensorFlow for production reliability

# Methods – Regularization

- Lasso regularization avoids overfitting and improves model stability
- The difference between the conditional log-likelihood,  $\ell(\boldsymbol{\theta})$ , and the lasso penalty,  $\lambda \|\boldsymbol{\theta}\|_1$ , provides penalized conditional log-likelihood

$$\ell_\lambda(\boldsymbol{\theta}) = \ell(\boldsymbol{\theta}) - \lambda \|\boldsymbol{\theta}\|_1$$

- The objective function  $\ell_\lambda(\boldsymbol{\theta})$  is maximized during training for a given hyperparameter  $\lambda$  (controlling the shrinkage on parameter vector  $\boldsymbol{\theta}$ )
- This hyperparameter is typically tuned via cross-validation

# Case Study

- Using the 2022 US Census of Agriculture data from Michigan
  - Used a subset of predictors – farm size and type, demographics
  - Compared a linear-logistic triple-system estimator (TSE) and new AITSE in terms of total farms and land in farms

# Bootstrap Simulation

- Used parametric bootstrap to simulate subsampled observations from Michigan TSE model (assuming historical-FSA list dependence)
- Fitted linear-logistic TSE and AITSE to bootstrapped data for testing (potential) nonlinear effects
- Calculated bias and variance for **total farms and land in farms**

# Simulation Results

- Total farms simulation – true value is 24,048

	TSE	AITSE
<b>Bias in total farms</b>	1.3%	-6.7%
<b>Simulation 2.5% quantile</b>	22,173	20,952
<b>Simulation 97.5% quantile</b>	27,413	23,807
<b>CV</b>	6.0%	3.4%

- Land in farms simulation – true value is 6,954,461

	TSE	AITSE
<b>Bias in total farms</b>	1.9%	-0.1%
<b>Simulation 2.5% quantile</b>	6,801,371	6,789,885
<b>Simulation 97.5% quantile</b>	7,676,946	7,156,600
<b>CV</b>	3.0%	1.3%

National Agricultural Statistics Service

# Conclusions

- It is not clear if AITSE outperforms TSE in terms of bias
- AITSE outperforms TSE in terms variance
- Referred records can be counted as a separate list if **record source** and **record linkage** data are retained
- Future research will assess calibration adjustments
